Information Theory

Chapter I: Discrete information sources

Block diagram of a communication system

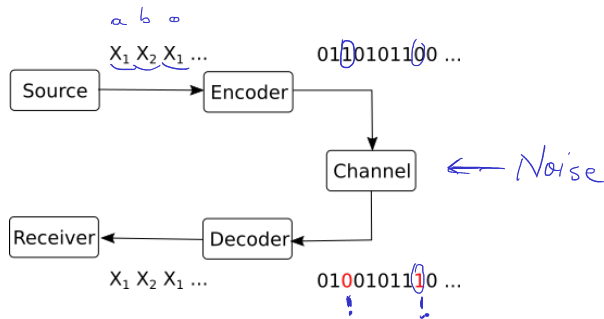

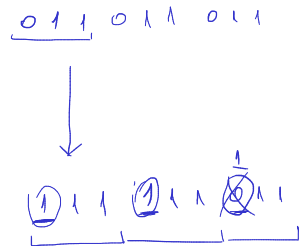

Figure 1: Block diagram of a communication system

- ▶ Source: creates information <u>messages</u> $X_1 \quad X_2 \quad X_3$
- ▶ Encoder: converts <u>messages</u> into symbols for transmission (i.e bits)
- ▶ Channel: delivers the symbols, introduces errors
- ▶ Decoder: detects/corrects the errors, rebuilds the information messages

What is information?

Example:

- Consider the sentence: "your favorite football team lost the last match"

- Does this message carry information? How, why, how much?

- Consider the following facts:
  - the message carries information only when you don't already know the result
  - if you already known the result, the message is useless (brings no information)
  - if the result was to be expected, there is little information. If the result is highly unusual, there is more information in this message (think betting)

Information and events

- We define the notion of **information** for a **probabilistic event**
    - the happening of a probabilistic event = creation of information
- Information brought by an event depends on the **probability** of the event
- Rule of thumb: if you can guess something most of the times, it has little information
- Questions:
    - does a sure event ($p = 1$) bring any information? $\longrightarrow \dot{i} = 0$
    - does an almost sure event (e.g. $P = 0.9999$) bring little or much information? $\longrightarrow \dot{i} = small$
    - does a rare event (e.g. $P = 0.0001$) bring a little or much information? $\longrightarrow \dot{i} = large$

Information

▶ The information attached to a particular <u>event</u> (known as "message")
  s_i is rigorously defined as:

$$i(s_i) = -\log_2(p(s_i))$$

$$i\left(\text{something}\right) = -\log_2\left(P\left(\text{something}\right)\right)$$

▶ Properties:
  ▶ $i(s_i) \geq 0$
  ▶ lower probability (rare events) means higher information
  ▶ higher probability (frequent events) means lower information
  ▶ a certain event brings no information: $-\log(1) = 0$
  ▶ an event with probability 0 brings infinite information (but it never
    happens...)
  ▶ for two independent events, their information gets added

$$i(\underbrace{p(s_i) \cdot p(s_j)}) = \underbrace{i(s_i)} + \underbrace{i(s_j)}$$

$$p(s_i) = 0.0001$$

$$i(s_i) = -\log_2(0.0001) = 13.2 \text{ bits}$$

$$-\log_2\left(\frac{1}{36}\right) = -\log_2\frac{1}{6} + \log_2\frac{1}{6}$$

The choice of logarithm

- Any base of logarithm can be used in the definition.
- Usual convention: use binary logarithm $\log_2()$
- In this case, the information $i(s_i)$ is measured in **bits**
- If using natural logarithm $ln()$, it is measured in *nats*.
- Logarithm bases can be converted to/from one another:

$$\log_b(x) = \frac{\log_a(x)}{\log_a(b)}$$

- Information defined using different logarithms differ only in scaling:

$$i_b(s_i) = \frac{i_a(s_i)}{\log_a(b)}$$

Information source

- A probabilistic <u>event</u> is always part of a set of <u>multiple events</u> (options)
    - e.g: a football team can win/lose/draw a match (3 possible events)
    - each event has a certain probability. All probabilities are known beforehand
    - at a given time, only one of the events can happen

- An **information source** = the set of all <u>events</u> together with <u>their</u> <u>probabilities</u>

- One event is called a **<u>message</u>**

- Each message carries the information that **it** happened, the quantity of information is dependent on its probability
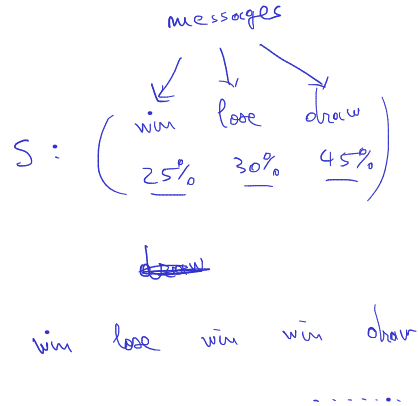

Sequence of messages

- An information source creates a **sequence of messages**
  - e.g. like throwing a coin or a dice several times in a row
- The probabilities of the messages are known and fixed
- Each time, a new message is randomly selected according to the probabilities

Discrete memoryless source

(information)

▶ A **discrete memoryless source** (DMS) is an information source which produces a sequence of **independent** messages

  ▶ i.e. the choice of a message at one time does not depend on the previous messages

▶ Each message has a fixed probability. The set of probabilities is the **distribution** of the source:

$$S : \begin{pmatrix} s_1 & s_2 & s_3 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix}$$

Discrete memoryless source

$$S : \begin{pmatrix} s_1 & s_2 & s_3 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix} \longleftarrow \text{discrete set}$$

▶ Terminology:

  ▶ <u>Discrete</u>: it can take a value from a discrete set ("alphabet")
  ▶ Co<u>mplete</u>: $\sum p(s_i) = 1$
  ▶ <u>Memoryless</u>: succesive values are independent of previous values
    (e.g. successive throws of a coin)

▶ A message from a DMS is also called a **random variable** in probabilistics.

Examples

▶ A coin is a discrete memoryless source (DMS) with two messages:

$$S : \begin{pmatrix} heads & tails \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix}$$

▶ A dice is a discrete memoryless source (DMS) with six messages:

$$S : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 & s_5 & s_6 \\ \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} \end{pmatrix}$$

▶ Playing the lottery can be modeled as DMS:

$$S : \begin{pmatrix} s_1 & s_2 \\ 0.9999 & 0.0001 \end{pmatrix}$$

Examples

▶ An extreme type of DMS containing the certain event:

$$S : \begin{pmatrix} s_1 & s_2 \\ 1 & 0 \end{pmatrix}$$

▶ Receiving an unknown *bit* (0 or 1) with equal probabilities:

$$S : \begin{pmatrix} 0 & 1 \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix} \longrightarrow H(S) = 1 \text{ bit}$$

- A DMS produces a sequence of messages by randomly selecting a message every time, with the same fixed probabilities

  - throwing a dice several times in a row you can get a sequence $4, 2, 3, 2, 1, 6, 1, 5, 4, 5 \ldots \ldots$

- If the sequence is very long (has N messages, N very large), each message s_i appears approximately $p(s_i) * N$ times in the sequence

  - gets more precise as $N \rightarrow \infty$

- We usually don't care about a single message. We are interested in long sequences of messages (think millions of bits of data)

- We are interested in the *average* information of a message from a DMS

- Definition: the **entropy** of a DMS source S is **the average information of a message**:

$$H(S) = \sum_k p(s_k)i(s_k) = -\sum_k p(s_k)\log_2(p_k)$$

bits/message

where $p(s_k)$ is the probability of message k

$$\left(0.6 \cdot 6_1 + 0.4 \cdot 6_2\right)$$

$$S : \begin{pmatrix} s_1 & s_2 \\ 3/4 & 1/4 \end{pmatrix}$$

$$i(s_1) = -\log_2\left(\frac{3}{4}\right) = 0.41 \, b$$

$$i(s_2) = -\log_2\left(\frac{1}{4}\right) = 2 \, b$$

$$s_1 \, s_2 \, s_1 \, s_1 \, s_2 \, s_1 \, s_2 \, s_2 \, s_1 \, s_1 \, \ldots$$

Average info. of one message:

$$\bar{i} = \frac{3}{4} \cdot 0.41 + \frac{1}{4} \cdot 2$$

$$= -\sum p(s_i) \cdot \log_2\left(p(s_i)\right)$$

- Since information of a message is measured in bits, entropy is measured in **bits** (or **bits / message**, to indicate it is an average value)

- Entropies using information defined with different logarithms differ only in scaling:

$$H_b(S) = \frac{H_a(S)}{\log_a(b)} \leftarrow \text{constant}$$

Examples

$$-\log \alpha = \log \frac{1}{\alpha}$$

$$\text{Coin}: \begin{pmatrix} \overset{0}{H} & \overset{1}{T} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix} \qquad \overset{0}{\underset{1}{\text{or}}} \qquad \log_2 \frac{1}{2} = \log_2 2^{-1} = -1$$

$$H(\text{coin}) = -\frac{1}{2} \underbrace{\log_2 \frac{1}{2}}_{-1} - \frac{1}{2} \cdot \underbrace{\log_2 \frac{1}{2}}_{-1} = \frac{1}{2} + \frac{1}{2} = 1 \text{ bit}$$

- Coin: $H(S) = 1 bit/message$

- Dice: $H(S) = \log(6) bits/message$ $\longrightarrow$

- Lottery: $H(S) = -0.9999 \log(0.9999) - 0.0001 \log(0.0001)$ $= \text{very small}$

- Receiving 1 bit: $H(S) = 1 bit/message$ (hence the name!)

$$S: \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} \end{pmatrix}$$

$$H(S) = -\frac{1}{6} \log \frac{1}{6} - \frac{1}{6} \log \frac{1}{6} - \cdots - \frac{1}{6} \log \frac{1}{6}$$

$$= -6 \cdot \frac{1}{6} \log \frac{1}{6} = -\log \frac{1}{6} = \log 6 = 2.5 \, b$$

$$S : \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} \end{pmatrix}$$

All the following interpretations of entropy are true:

- H(S) is the *average* *uncertainty* of the source S

- H(S) is the *average* *information* of the messages from source S

- A long sequence of N messages from S has total information $\approx N \cdot H(S)$

→ - H(S) is the minimum number of bits (0,1) required to uniquely represent an average message from source S

$$\Lambda_1 \; \Delta_2 \; \Lambda_6 \; \Delta_2 \; \Delta_1 \; \ldots \ldots \; .$$

$$\underbrace{\qquad\qquad\qquad\qquad}_{N \text{ messages}}$$

$$I =$$

Properties of entropy

$p_k \in [0, 1]$

$\log_2 x' = \frac{\ln x'}{\ln 2}$

$H(s) = -\sum_k \underbrace{p_k}_{\geq 0} \cdot \underbrace{\log(p_k)}_{\leq 0} \geq 0$

We prove the following **properties of entropy**:

1. $H(S) \geq 0$ (non-negative)
   Proof: via definition

2. $H(S)$ is maximum when all n <u>messages have equal probability</u> $\frac{1}{n}$. The maximum value is $\max H(S) = \log(n)$

   Proof: only for the case of 2 messages, use <u>derivative</u> in definition

3. <u>*Diversification*</u> of the source always increases the entropy

   Proof: compare entropies in both cases

$S : \begin{pmatrix} \Delta_1 & \Delta_2 & \Delta_3 \\ p_1 & p_2 & p_3 \\ 1/3 & 1/3 & 1/3 \end{pmatrix}$ $p_1 + p_2 + p_3 = 1$

$S : \begin{pmatrix} \Delta_1 & \Delta_2 \\ p & 1-p \end{pmatrix}$

$H(s) = -p \log p - (1-p) \log(1-p)$

Want maximum ↑

$\frac{d\, H(s)}{dp} = 0$ TO DO next week

$-\log p - \frac{p \cdot 1}{p \cdot \ln 2} + \log(1-p) + (1-p)\frac{1}{(1-p)\ln 2} = 0$

$-\log p + \log 1-p = 0 \iff \log_2 \frac{1-p}{p} = 0 \iff \frac{1-p}{p} = 1 \iff 1-p = p$

$2^{\log_2 \frac{1-p}{p}} = 2^0$

$\iff \boxed{p = \frac{1}{2}}$

The entropy of a binary source

▶ Consider a general DMS with two messages:

$$S : \begin{pmatrix} s_1 & s_2 \\ p & 1-p \end{pmatrix}$$

▶ It's entropy is:

$$H(S) = -p \cdot \log(p) - (1-p) \cdot \log(1-p)$$

Figure 2: Entropy of a binary source

Prove 3rd property:

3) $S : \begin{pmatrix} \Delta_1 & \Delta_2 \cdots & \Delta_M \\ p_1 & p_2 & p_M \end{pmatrix}$

$H(S_d) \geq H(S)$

$S_d : \begin{pmatrix} \Delta_1 & \Delta_2 \cdots & \Delta_{M_1} & \Delta_{M_2} \\ p_1 & p_2 & p_{M_1} & p_{M_2} \end{pmatrix}$

$P_M = P_{M_1} + P_{M_2}$

$H(S) = -p_1 \log_2 p_1 - \cdots - P_M \cdot \log P_M$

$H(S_d) = -p_1 \log_2 p_1 - \cdots - p_{M_1} \log p_{M_1} - p_{M_2} \log p_{M_2}$

$H(S_d) - H(S) = -p_{M_1} \log p_{M_1} - p_{M_2} \log p_{M_2} + (p_{M_1} + p_{M_2}) \log(p_{M_1} + p_{M_2})$

$= p_{M_1} \cdot \left(\log(p_{M_1} + p_{M_2}) - \log p_{M_1} \right) + p_{M_2} \cdot \left(\log(p_{M_1} + p_{M_2}) - \log p_{M_2} \right)$

$= p_{M_1} \cdot \log \frac{p_{M_1} + p_{M_2}}{p_{M_1}} + p_{M_2} \cdot \log \frac{p_{M_1} + p_{M_2}}{p_{M_2}} \geq 0$

q.e.d.

Game: I think of a number between 1 and 8. You have to guess it by asking yes/no questions.

→ ▶ How much uncertainty does the problem have?
  ▶ How is the best way to ask questions? Why?
  ▶ What if the questions are not asked in the best way?
 ▶ On average, what is the number of questions required to find the number?

$$S : \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ 1/8 & 1/8 & 1/8 & 1/8 & 1/8 & 1/8 & 1/8 & 1/8 \end{pmatrix}$$

$$H(S) = -\frac{8 \cdot 1}{8} \log_2 \frac{1}{8} = \log_2 8 = 3 \text{ bits}$$

1) Is it odd or even?

$$\text{Answer:} \begin{pmatrix} \text{Yes} & \text{No} \\ 1/2 & 1/2 \end{pmatrix} \rightarrow H(\text{Answer}) = 1 \text{ bit}$$

Decision Tree

Odd or Even?
  No — Yes
        Is it ≥ 4?
              No — Yes
        Is it 2?
          No — Yes
        (4) (2)

Is it 1?

$$\text{Answer:} \begin{pmatrix} \text{Yes} & \text{No} \\ 1/8 & 7/8 \end{pmatrix} \Rightarrow H(\text{Answer}) < 1$$

Example - Game v2

▶ Suppose I choose a number according to the following distribution:

$$H(S) = -\frac{1}{2}\log\frac{1}{2} - \frac{1}{4}\log\frac{1}{4} - 2 \cdot \frac{1}{8}\log\frac{1}{8}$$

$$= \frac{1}{2} + \frac{1}{2} + \frac{3}{4} = \frac{7}{4} \text{ bits}$$

$$= 1.75$$

$$S : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{8} & \frac{1}{8} \end{pmatrix}$$

Is it > 2

Yes   No

$\frac{6}{8}$ $\frac{2}{8}$

- ▶ On average, what is the number of questions required to find the number?
- ▶ What questions would you ask?

▶ What if the distribution is:

$$S : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \\ 0.14 & 0.29 & 0.4 & 0.17 \end{pmatrix}$$

Is it 1 or 3

▶ In general:

- ▶ What distribution makes guessing the number the most difficult?
- ▶ What distribution makes guessing the number the easiest?

optimal Decision Tree?

Is it 1?

No $\frac{1}{2}$ Yes $\frac{1}{2}$

Is it 2?   (1)

No $\frac{1}{2}$ Yes $\frac{1}{2}$

Is it 3?   (2)

No   Yes

(4)   (3)

Efficiency and redundancy

▶ Efficiency of a DMS:

$$\eta = \frac{H(S)}{H_{max}} = \frac{H(S)}{\log(n)}$$

▶ Absolute redundancy of a DMS:

$$R = H_{max} - H(S)$$

▶ Relative redundancy of a DMS:

$$\rho = \frac{H_{max} - H(S)}{H_{max}} = 1 - \eta$$

Information flow of a DMS

- Suppose that message s_i takes time t_i to be transmitted via some channel.

- Definition: the **information flow** of a DMS S is the average information transmitted per unit of time:

$$H_\tau(S) = \frac{H(S)}{\bar{t}} \quad \longleftarrow \text{ average transmission time of messages}$$

where $\bar{t}$ is the average duration of transmitting a message:

$$\bar{t} = \sum_i p_i t_i$$

- Measured in **bps** (bits per second)
- Important for data communication

Distance between distributions

▶ How to measure how similar / how different are two distributions?

  ▶ must have the same number of messages
  ▶ example: $p(s_1), \ldots p(s_n)$ and $q(s_1), \ldots q(s_n)$

▶ **Definition**: the **Kullback–Leibler distance** of two distributions P and Q is

$$D_{KL} = D_{KL}(P||Q) = \sum_i p(s_i) \log\left(\frac{p(s_i)}{q(s_i)}\right)$$

▶ It is a way to measure the **distance (difference)** between two distributions

▶ Also known as *relative entropy*, or the Kullback-Leibler *divergence*

$$S_1: \begin{pmatrix} D_1 & D_2 & D_3 \\ 0.5 & 0.2 & 0.3 \end{pmatrix}$$

$$S_2: \begin{pmatrix} D_1 & D_2 & D_3 \\ 0.51 & 0.18 & 0.31 \end{pmatrix}$$

$$S_3: \begin{pmatrix} D_1 & D_2 & D_3 \\ 0.52 & 0.18 & 0.3 \end{pmatrix}$$

$$\begin{pmatrix} p_1 & p_2 & \cdots & p_n \\ q_1 & q_2 & \cdots & q_2 \end{pmatrix}$$

$$= p_1 \log \frac{p_1}{q_1} + p_2 \log \frac{p_2}{q_2} + \cdots$$

Properties of Kullback-Leibler distance

▶ Properties:
  ▶ $D_{KL}(P||Q)$ is always ≥ 0, and is equal to 0 only when P and Q are the same
  ▶ the higher $D_{KL}(P||Q)$ is, the more different the distributions are
  ▶ it is **not commutative**: $D_{KL}(P||Q) \neq D_{KL}(Q||P)$

▶ Example: at whiteboard

▶ Example usage: classification systems (cross-entropy loss)

$$S : \begin{pmatrix} \Delta_1 & \Delta_2 & \Delta_3 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \end{pmatrix}$$

▶ Definition: the **n-th order extension** of a DMS S, S^n is a source which has as messages all the combinations of n messages of S:

$$S^2 : \begin{pmatrix} \Delta_1\Delta_1 & \Delta_1\Delta_2 & \Delta_1\Delta_3 & \Delta_2\Delta_1 & \Delta_2\Delta_2 & \Delta_2\Delta_3 & \Delta_3\Delta_1 & \Delta_3\Delta_2 & \Delta_3\Delta_3 \\ \frac{1}{4} & \frac{1}{8} & \frac{1}{8} & \frac{1}{8} & \frac{1}{16} & \frac{1}{16} & \frac{1}{8} & \frac{1}{16} & \frac{1}{16} \end{pmatrix}$$

$$\sigma_i = \underbrace{s_j s_k ... s_l}_{n}$$

▶ If S has k messages, S^n has k^n messages

▶ Since S is DMS, probabilities multiply:

$$p(\sigma_i) = \underbrace{p(s_j) \cdot p(s_k) \cdot ... \cdot p(s_l)}_{n}$$

▶ Examples:

$$S : \begin{pmatrix} s_1 & s_2 \\ \frac{1}{4} & \frac{3}{4} \end{pmatrix}$$

$$S^2 : \begin{pmatrix} \sigma_1 = s_1 s_1 & \sigma_2 = s_1 s_2 & \sigma_3 = s_2 s_1 & \sigma_4 = s_2 s_2 \\ \frac{1}{16} & \frac{3}{16} & \frac{3}{16} & \frac{9}{16} \end{pmatrix}$$

$$S^3 : \begin{pmatrix} s_1 s_1 s_1 & s_1 s_1 s_2 & s_1 s_2 s_1 & s_1 s_2 s_2 & s_2 s_1 s_1 & s_2 s_1 s_2 & s_2 s_2 s_1 & s_2 s_2 s_2 \\ ... & ... & ... & ... & ... & ... & ... & ... \end{pmatrix}$$

$$18 \cdot H(s) = 9 \cdot H(s^2) = 2.25 \cdot H(s^8)$$

$$S : \begin{pmatrix} 0 & 1 \\ 1/2 & \frac{1}{2} \end{pmatrix} \quad H(s) = 1 \text{ bit}$$

18 messages from $\longrightarrow$

9 messages from $\longrightarrow S^2 : \begin{pmatrix} 00 & 01 & 10 & 11 \\ \cdot & \cdot & \cdot & \cdot \end{pmatrix}$

- Long sequence of binary messages:

$$\underbrace{010011001110010100}...$$

messages from $\rightarrow S^8 : \begin{pmatrix} 00000000 & & & 11111111 \\ \cdot \cdot & & & \cdot \cdot \end{pmatrix}$

- Can be grouped in bits, half-bytes, bytes, 16-bit words, 32-bit long words, and so on

- Can be considered:

  - N messages from a binary source (with 1 bit), or
  - N/2 messages from a source with 4 messages (with 2 bits)...
  - etc

$$H(s^8) = 8 \cdot H(s)$$
$$= 8 \text{ bits}$$

Proof:

$$S : \begin{pmatrix} \Delta_1 & \Delta_2 & \cdots & \Delta_N \\ p_1 & p_2 & & p_N \end{pmatrix}$$

$$S^n \doteq \begin{pmatrix} \sigma_1 & \sigma_2 & \cdots & \sigma_{N^n} \\ p(\sigma_1) & p(\sigma_2) & & p(\sigma_{N^n}) \end{pmatrix}$$

$$H(S^n) = -\sum_{i=1}^{N^n} P(\sigma_i) \cdot \log\left(P(\sigma_i)\right) = -\sum_{j=1}^{N}\sum_{k=1}^{N}\cdots\sum_{\ell=1}^{N} \left(P_j \cdot P_k \cdot \ldots \cdot P_\ell\right) \cdot \log\left(P_j \cdot P_k \cdot \ldots \cdot P_\ell\right)$$

$$\left(\log P_j + \log P_k \cdots + \log P_k \atop n\ terms\right)$$

$$= -\sum_{j=1}^{N}\sum_{k=1}^{N}\cdots\sum_{\ell=1}^{N} \left(P_j \cdot P_k \cdot \ldots \cdot P_\ell\right) \cdot \log P_j$$

n terms $\Bigg\{$

$$+ \sum_{j=1}^{N}\sum_{k=1}^{N}\cdots\sum_{\ell=1}^{N} \left(P_j \cdot P_k \cdot \ldots \cdot P_\ell\right) \cdot \log P_k +$$

$$+ \ldots + \sum_{j=1}^{N}\sum_{k=1}^{N}\cdots\sum_{\ell=1}^{N} \left(P_j \cdot P_k \cdot \ldots \cdot P_\ell\right) \cdot \log P_\ell =$$

▶ Theorem: The entropy of a *n*-th order extension is *n* times larger than the entropy of the original DMS

$$H(S^n) = nH(S)$$

▶ Interpretation: grouping messages from a long sequence in blocks of *n* does not change total information (e.g. groups of 8 bits = 1 byte)

$$= -\sum_j P_j \log P_j \underbrace{\sum_k P_k \cdots \sum_{\ell=1}^{N} P_\ell}_{1} + \sum_j P_j \underbrace{\sum_k P_k \log P_k}_{H(S)} \cdots - \ldots - \sum_j P_j \sum_k P_k \cdots \sum_\ell P_\ell \log P_\ell$$

H(S) … H(S)

$$= n \cdot H(S)$$

▶ The distribution (frequencies) of letters in English:

letter	probability	letter	probability
A	.082	N	.067
B	.015	O	.075
C	.028	P	.019

▶ Text from a memoryless source with these probabilities:

OCRO HLI RGWR NMIELWIS EU LL NBNESEBYA TH EEI
ALHENHTTPA OOBTTVA NAH BRL

(taken from Elements of Information Theory, Cover, Thomas)

▶ What's wrong? **Memoryless**

Sources with memory

▶ **Definition**: A source has **memory of order** m if the probability of a message depends on the last m messages.

▶ The last m messages = the **state** of the source (notation S_i).

▶ A source with n messages and memory $m => $ has n^m states in all.

▶ For every state, messages can have a different set of probabilities. Notation: $p(s_i|S_k)$ = "*probability of s_i in state S_k*".

▶ Also known as *Markov sources*.

$$S : \begin{pmatrix} \Delta_1 & \Delta_2 \end{pmatrix}$$

memory $= 2$

How many states?

$\Delta_1 \Delta_1 = S_L$

$\Delta_1 \Delta_2 = S_2$

$\Delta_2 \Delta_1 = S_3$

$\Delta_2 \Delta_2 = S_4$

Last 2 messages = state

$\underbrace{\Delta_1 \Delta_2}_{S_2} \underbrace{\Delta_2}_{S_4}$

$P(\Delta_2|S_2) \;(=) \; P(S_4|S_2)$

state old

$P(S_3|S_4) = P(\Delta_2|S_4)$

$\underbrace{\Delta_2 \Delta_2}_{S_4} \underbrace{\Delta_1}_{S_3}$

Example

▶ A source with $n = 4$ messages and memory $m = 1$

"if the source is in state S_1"

▶ if last message was s_1, choose next message with distribution

States →

state

$S_1 : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \\ 0.4 & 0.3 & 0.2 & 0.1 \end{pmatrix}$ ⟹ $H(S_1) = -\sum P_k \cdot \log P_k$

▶ if last message was s_2, choose next message with distribution

state

$S_2 : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \\ 0.33 & 0.37 & 0.15 & 0.15 \end{pmatrix}$

"prob. of s_3 if source is in state S_2"

$P(s_3 \mid S_2)$

"conditioned by"

▶ if last message was s_3, choose next message with distribution

state

$S_3 : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \\ 0.2 & 0.35 & 0.41 & 0.04 \end{pmatrix}$

▶ if last message was s_4, choose next message with distribution

state

$S_4 : \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \\ 0.1 & 0.2 & 0.3 & 0.4 \end{pmatrix}$

$(S) = \begin{pmatrix} s_1 & s_2 & s_3 & s_4 \end{pmatrix}$

$P(s_3)$

s_1
s_2
s_3
s_4

$P(S_1 \mid S_1) = 0.4$

$P(S_2 \mid S_1) = 0.3$

▶ When a new message is provided, the source **<u>transitions</u>** to a new state:
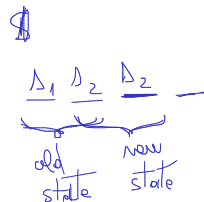

$$\dots \underbrace{s_i s_j s_k}_{\text{old state}} \underline{s_l}$$

$$\dots s_i \underbrace{s_j s_k s_l}_{\text{new state}}$$

▶ The message probabilities = the probabilities of transitions from some state S_u to another state S_v

▶ The transition probabilities are organized in a **<u>transition matrix</u>** $[T]$

$$[T] = \overset{old}{\underset{state}{}}\begin{bmatrix} p_{11} & p_{12} & \dots & p_{1N} \\ p_{21} & p_{22} & \dots & p_{2N} \\ \dots & \dots & \dots & \dots \\ p_{N1} & p_{N2} & \dots & p_{NN} \end{bmatrix}$$

new state

$$P_{k\ell} = P(S_\ell \mid S_k)$$

▶ p_{ij} is the transition probability from state $\underline{S_i}$ to state $\underline{S_j}$ $= P(S_j \mid S_i)$

▶ N is the total number of states

Graphical representation

$$\begin{pmatrix} a\ c\ c\ e\ \_ \\ p : 1\ 0\ 0 \\ \ell : 1\ 0\ 1 \\ u : 1\ 1\ 0 \\ \qquad : 1\ 1 \end{pmatrix}$$

$S_1\ S_1\ \_$
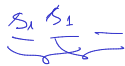

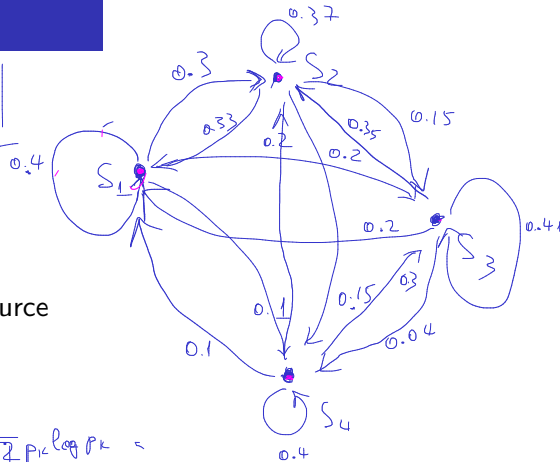

$S_0\ S_2$

Sum of output transitions = 1

At whiteboard: draw states and transitions for previous example (source with $n = 4$ messages and memory $m = 1$)

$$T = \begin{array}{c|cccc} & S_1 & S_2 & S_3 & S_4 \\ \hline S_1 & 0.4 & 0.3 & 0.2 & 0.1 \\ S_2 & 0.33 & 0.37 & 0.15 & 0.15 \\ S_3 & 0.2 & 0.35 & 0.41 & 0.04 \\ S_4 & 0.1 & 0.2 & 0.3 & 0.4 \end{array}$$

old / new

$\to H(S_1) = -\overline{\sum} p_k \log p_k =$

$\to H(S_2) =$

$\to H(S_3) =$

$\to H(S_4) =$

4×4

$\boxed{61\ 77\ 0}$

Entropy of sources with memory

- What entropy does a source with memory have?

- Each state S_k has a different distribution $->$ each state has a different entropy $H(S_k)$

$$H(S_k) = -\sum_i p(s_i|S_k) \cdot \log(p(s_i|S_k))$$

- Global entropy = average entropy

$$H(S) = \sum_k p_k H(S_k)$$

where p_k = probability that the source is in state S_k

- (i.e. after a very long sequence of messages, the fraction of time when the source was in state S_k)

$P_1 \simeq 90\%$ $P_2 = 10\%$

$H(S_1)$ $H(S_2)$

$H(S_1) = 90\% \ H(S_1) + 10\% \ H(S_2)$

- How to find out the weights p_k?
- They are known as the **stationary probabilities**
- p_k = probability that the source is in state S_i, after running for a very long time
  - (i.e. after a very long sequence of messages, the fraction of time when the source was in state S_k)
- We need to answer the following question:

  If we know the state S_k at time n, what will be the state at time $n + 1$?

Ergodic sources

- Let $p_i^{(n)}$ = the probability that source S is in state S_i at time n.

- In what state will it be at time $n+1$? (after one more message)
  - i.e. what are the probabilities of the states at time $n+1$?

- Just multiply with T

$$[p_1^{(n)}, p_2^{(n)}, ..., p_N^{(n)}] \cdot [T] = [p_1^{(n+1)}, p_2^{(n+1)}, ..., p_N^{(n+1)}]$$

at time n at time $n+1$

- After one more message:

$$[p_1^{(n)}, p_2^{(n)}, ..., p_N^{(n)}] \cdot [T] \cdot [T] = [p_1^{(n+2)}, p_2^{(n+2)}, ..., p_N^{(n+2)}]$$

- For every new moment of time, one more multiplication with T

$$P\left(S_1 \text{ after } 1 \text{ step} \right) = P_1 \cdot P_{11} + P_2 \cdot P_{21} + P_3 \cdot P_{31} + P_4 \cdot P_{41}$$
$$P\left(S_2 \right)$$

$n : \quad S_2$

$n+1 : \left\{ \begin{array}{cccc} S_1 & S_2 & S_3 & S_4 \\ 0.33 & 0.37 & 0.15 & 0.15 \end{array} \right\}$

$[0 \ 1 \ 0 \ 0] \cdot \left[\quad T \quad \right] = [0.33 \ 0.37 \ 0.15 \ 0.15]$

time n time $n+1$

$[P_1 \ P_2 \ P_3 \ P_4] \cdot \quad = [$

▶ In general, starting from <u>time 0</u>, after n messages the probabilities that the source is in a certain state are:

$$[p_1^{(0)}, p_2^{(0)}, ..., p_N^{(0)}] \cdot [T]^n = [p_1^{(n)}, p_2^{(n)}, ..., p_N^{(n)}]$$

initially   after time n
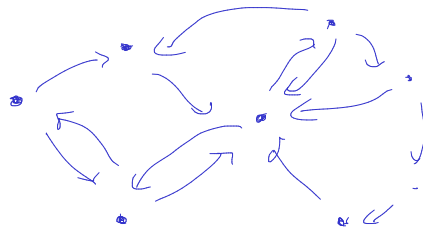

- A source is called **ergodic** if every state can be reached from every state, in a finite number of steps.

- Property of ergodic sources:
  - After many messages, the probabilities of the states *become stationary* (converge to some fixed values), irrespective of the initial probabilities (no matter what state the source started from initially)

$$\lim_{n \to \infty} [p_1^{(n)}, p_2^{(n)}, ... p_N^{(n)}] = [p_1, p_2, ... p_N]$$

Finding the stationary probabilties

- How to find the value of the stationary probabilities?

- When n is very large, after n messages and after $n+1$ messages the probabilities are the same:

$$[p_1, p_2, ... p_N] \cdot [T] = [p_1, p_2, ... p_N]$$

at time n at time $n+1$

(handwritten: system with N unknowns (p_k) and N equations / if $n \to \infty$)

- This is an equation system in matrix form

- One line should be removed (linear combination), and replaced with:

$$p_1 + p_2 + ... + p_N = 1$$

- Solve the resulting system of equations, find values of p_k

► The entropy of an ergodic source with memory is

$$H(S) = \sum_k p_k H(S_k) = -\sum_k p_k \sum_i p(s_i|S_k) \cdot \log(p(s_i|S_k))$$

$$H(S_k)$$

Exercise

1. Consider a discrete source with memory, with the graphical representation given below. The states are defined as follows: $S_1 : s_1 s_1$, $S_2 : s_1 s_2$, $S_3 : s_2 s_1$, $S_4 : s_2 s_2$.

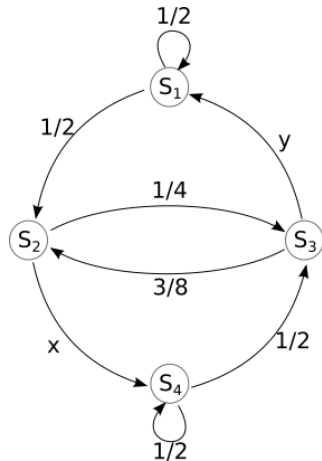

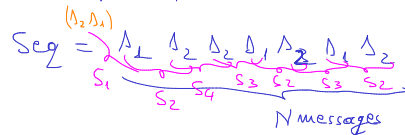

Figure 3: Graphical representation of the source

How to compute prob. of a sequence:

$$Seq = \underset{S_1}{\overset{(\Delta_2 \Delta_1)}{\Delta_1}} \underset{S_2}{\Delta_2} \underset{S_4}{\Delta_2} \underset{S_3}{\Delta_1} \underset{S_2}{\Delta_2} \underset{S_3}{\Delta_1} \underset{S_2}{\Delta_2}$$

N messages

1) Memoryless Source:

$$P(Seq) = \underbrace{P(\Delta_1) \cdot P(\Delta_2) \cdot \ldots \cdot P(\Delta_2)}_{N}$$

2). With memory :

- Convert seq. of messages into seq of states.
- Initial condition : initial state

Assume initial state is S_3

$$\underset{\text{initial}}{S_3} S_1 \; S_2 \; S_4 \; S_3 \; S_2 \; S_3 \; S_2$$

get them from T

$$P(Seq) = P(S_1 | S_3) \cdot P(S_2 | S_1) \cdot P(S_4 | S_2) \cdot \ldots \cdot P(S_2 | S_3)$$

Questions:

a. What are the values of x and y?
b. Write the transition matrix $[T]$;
c. Compute the entropy in state S_4;
d. Compute the global entropy of the source;
e. What are the memory order, m, and the number of messages of the source, n?
f. If the source is initially in state S_2, in what states and with what probabilities will the source be after 2 messages?

Example English text as sources with memory

$$S : \begin{pmatrix} A \cdots\cdots Z \, \sqcup \end{pmatrix}$$

(taken from Elements of Information Theory, Cover, Thomas)

▶ Memoryless source, equal probabilities:

XFOML RXKHRJFFJUJ ZLPWCFWKCYJ
FFJEYVKCQSGXYD QPAAMKBZAACIBZLHJQD

▶ Memoryless source, probabilities of each letter as in English:

OCRO HLI RGWR NMIELWIS EU LL NBNESEBYA TH EEI
ALHENHTTPA OOBTTVA NAH BRL

▶ Source with memory $m = 1$, frequency of pairs as in English:

ON IE ANTSOUTINYS ARE T INCTORE ST BE S DEAMY
ACHIN D ILONASIVE TUCOOWE AT TEASONARE EUSO
TIZIN ANDY TOBE SEACE CTISBE

$$A \quad \cancel{A}$$

► Source with memory $m = 2$, frequency of triplets as in English:

IN NO IST LAT WHEY CRATICT FROURE BERS GROCID
PONDENOME OF DEMONSTURES OF THE REPTAGIN IS
REGOACTIONA OF CRE

► Source with memory $m = 3$, frequency of 4-plets as in English:

THE GENERATED JOB PROVIDUAL BETTER TRAND THE DISPLAYED
CODE, ABOVERY UPONDULTS WELL THE CODERST IN THESTICAL
IT DO HOCK BOTHE MERG. (INSTATES CONS ERATION. NEVER
ANY OF PUBLE AND TO THEORY. EVENTIAL CALLEGAND TO ELAST
BENERATED IN WITH PIES AS IS WITH THE)

NEW ?

EVE

Example application

- Suppose we receive a text with random missing letters

- We need to fill the blanks with the appropriate letters

- How?
    - build a model: source with memory of some order
    - fill the missing letter with the most likely letter given by the model

Chapter summary

- Information of a message: $i(s_k) = -\log_2(p(s_k))$

- Entropy of a memoryless source:
  $H(S) = \sum_k p_k i(s_k) = -\sum_k p_k \log_2(p_k)$

- Properties of entropy:

    1. $H(S) \geq 0$

    2. Is maximum when all messages have equal probability
       ($H_{max}(S) = \log(n)$)

    3. *Diversfication* of the source always increases the entropy

- Sources with memory: definition, transitions

- Stationary probabilities of ergodic sources with memory:
  $[p_1, p_2, ...p_N] \cdot [T] = [p_1, p_2, ...p_N]$, $\sum_i p_i = 1$.

- Entropy of sources with memory:
  $$H(S) = \sum_k p_k H(S_k) = -\sum_k p_k \sum_i p(s_i|S_k) \cdot \log(p(s_i|S_k)$$
